Abstract

We consider the problem of text representation and categorization. Conventionally, a text document is represented by a vector in high dimensional space. Some learning algorithms are then applied in such a vector space for text categorization. Particularly, Support Vector Machine (SVM) has received a lot of attentions due to its effectiveness. In this paper, we propose a new classification algorithm called Support Tensor Machine (STM). STM uses Tensor Space Model to represent documents. It considers a document as the second order tensor in $\mathbb{R}^{n_1} \otimes \mathbb{R}^{n_2}$, where $\mathbb{R}^{n_1}$ and $\mathbb{R}^{n_2}$ are two vector spaces. With tensor representation, the number of parameters estimated by STM is much less than the number of parameters estimated by SVM. Therefore, our algorithm is especially suitable for small sample cases. We compared our proposed algorithm with SVM for text categorization on two standard databases. Experimental results show the effectiveness of our algorithm.

1 INTRODUCTION

Text categorization is a task of assigning category labels to new documents based on a set of pre-labelled documents. It is usually considered as a supervised or semi-supervised learning problem. During the last decade, a lot of learning algorithms have been proposed for text categorization, such as Support Vector Machines (SVM) [7], naive bayes [9], k-nearest neighbors and linear least square fit [19]. Most of these works are based on the Vector Space Model (VSM, [13]). The documents are represented as vectors, and each word corresponds to a dimension. The main reason of the popularity of VSM is probably due to the fact that most of the existing learning algorithms can only take vectors as their inputs, rather than tensors.

* The work was supported in part by the U.S. National Science Foundation NSF IIS-03-08215/IIS-05-13678. Any opinions, findings, and conclusions or recommendations expressed in this paper are those of the authors and do not necessarily reflect the views of the funding agencies.
Support Vector Machines (SVM) is a relatively new learning approach introduced by Vapnik in 1995 for solving two-class pattern recognition problem [15]. It is based on the Structural Risk Minimization principle for which error-bound analysis has been theoretically motivated. The method is defined over a vector space where the problem is to find a decision surface that maximizes the margin between the data points in a training set. Previous investigations have demonstrate that SVM can be superior to other learning algorithms such as naïve bayes [18].

In supervised learning settings with many input features, overfitting is usually a potential problem unless there is ample training data. For example, it is well known that for unregularized discriminative models fit via training-error minimization, sample complexity (i.e., the number of training examples needed to learn “well”) grows linearly with the Vapnik-Chernovenkis (VC) dimension. Further, the VC dimension for most models grows about linearly in the number of parameters [14], which typically grows at least linearly in the number of input features. All these reasons lead us to consider new representations and corresponding learning algorithms with less number of parameters.

In this paper, we propose a novel supervised learning algorithm for text categorization, which is called Support Tensor Machine (STM). Different from most of previous text categorization algorithms which consider a document as a vector in $\mathbb{R}^n$ based on the vector space model, STM considers a document as a second order tensor in $\mathbb{R}^{n_1} \otimes \mathbb{R}^{n_2}$, where $n_1 \times n_2 \approx n$. For example, a vector $x \in \mathbb{R}^n$ can be transformed by some means to a second order tensor $X \in \mathbb{R}^{n_1} \otimes \mathbb{R}^{n_2}$. A linear classifier in $\mathbb{R}^n$ can be represented as $a^T x + b$ in which there are $n + 1 \approx n_1 \times n_2 + 1$ parameters ($b, a_i, i = 1, \cdots, n$). Similarly, a linear classifier in the tensor space $\mathbb{R}^n \otimes \mathbb{R}^n$ can be represented as $u^T X v + b$ where $u \in \mathbb{R}^{n_1}$ and $v \in \mathbb{R}^{n_2}$. Thus, there are only $n_1 + n_2 + 1$ parameters. This property makes STM especially suitable for small sample cases.

Recently there has been a lot of interests in tensor based approaches to data analysis in high dimensional spaces. Vasilescu and Terzopoulos have proposed a novel face representation algorithm called Tensorface [16]. Tensorface represents the set of face images by a higher-order tensor and extends Singular Value Decomposition (SVD) to higher-order tensor data. Some other researchers have also shown how to extend Principal Component Analysis, Linear Discriminant Analysis, and Locality Preserving Projection to higher order tensor data [2], [6], [20]. Most of previous tensor based learning algorithms are focused on dimensionality reduction. In this paper, we extend SVM based idea to tensor data for classification.

It is worthwhile to highlight several aspects of the proposed approach here:

- While traditional linear classification algorithms like SVM find a classifier in $\mathbb{R}^n$, STM finds a classifier in tensor space $\mathbb{R}^{n_1} \otimes \mathbb{R}^{n_2}$. This leads to structured classification.

- The computation of STM is very simple. It can be obtained by solving two quadratic optimization problems. For each single optimization problem, the computational complexity approximately scales with $\sqrt{n}$, where $n$ is the dimensionality of the document space. There
are few parameters that are independently estimated, so performance in small data sets is very good.

- This paper is primarily focused on the second order tensors. However, the algorithm and the analysis presented here can also be applied to higher order tensors.

The rest of this paper is organized as follows: Section 2 provides a brief description of the algebra of tensors and SVM. In Section 3, we give some descriptions on tensor space model for document representation. The Support Tensor Machine (STM) approach for text categorization is described in Section 4. In Section 5, we give a theoretical justification of STM and its connections to SVM. The experimental results on text databases are presented in Section 6. Finally, we provide some concluding remarks and suggestions for future work in Section 7.

2 PRELIMINARY

In this section, we provide a brief overview of the algebra of tensors and Support Vector Machine. For a detailed treatment please see [8], [15].

2.1 The Algebra of Tensors

A tensor with order $k$ is a real-valued multilinear function on $k$ vector spaces:

$$T : \mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_k} \rightarrow \mathbb{R}$$

The number $k$ is called the order of $T$. A multilinear function is linear as a function of each variable separately. The set of all $k$-tensors on $\mathbb{R}^{n_i}, i = 1, \cdots, k$, denoted by $T^k$, is a vector space under the usual operations of pointwise addition and scalar multiplication:

$$(aT)(a_1, \cdots, a_k) = a (T(a_1, \cdots, a_k)),$$

$$(T + T')(a_1, \cdots, a_k) = T(a_1, \cdots, a_k) + T'(a_1, \cdots, a_k)$$

where $a_i \in \mathbb{R}^{n_i}$. Given two tensors $S \in T^k$ and $T \in T^l$, define a map:

$$S \otimes T : \mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_{k+l}} \rightarrow \mathbb{R}$$

by

$$S \otimes T(a_1, \cdots, a_{k+l}) = S(a_1, \cdots, a_k)T(a_{k+1}, \cdots, a_{k+l})$$

It is immediate from the multilinearity of $S$ and $T$ that $S \otimes T$ depends linearly on each argument $a_i$ separately, so it is a $(k + l)$-tensor, called the tensor product of $S$ and $T$.

For the first order tensors, they are simply the covectors on $\mathbb{R}^{n_1}$. That is, $T^1 = \mathcal{R}^{n_1}$, where $\mathcal{R}^{n_1}$ is the dual space of $\mathbb{R}^{n_1}$. The second order tensor space is a product of two first order tensor spaces,
\[ T^2 = \mathcal{R}^{n_1} \otimes \mathcal{R}^{n_2} \]

Let \( \mathbf{e}_1, \ldots, \mathbf{e}_{n_1} \) be the standard basis of \( \mathcal{R}^{n_1} \), and \( \varepsilon_1, \ldots, \varepsilon_{n_1} \) be the dual basis of \( \mathcal{R}^{n_1} \) which is formed by coordinate functions with respect to the basis of \( \mathcal{R}^{n_1} \). Likewise, let \( \tilde{\mathbf{e}}_1, \ldots, \tilde{\mathbf{e}}_{n_2} \) be a basis of \( \mathcal{R}^{n_2} \), and \( \tilde{\varepsilon}_1, \ldots, \tilde{\varepsilon}_{n_2} \) be the dual basis of \( \mathcal{R}^{n_2} \). We have,

\[ \varepsilon_i(\mathbf{e}_j) = \delta_{ij} \quad \text{and} \quad \tilde{\varepsilon}_i(\tilde{\mathbf{e}}_j) = \delta_{ij} \]

where \( \delta_{ij} \) is the kronecker delta function. Thus, \( \{ \varepsilon_i \otimes \tilde{\varepsilon}_j \} \) \( (1 \leq i \leq n_1, 1 \leq j \leq n_2) \) forms a basis of \( \mathcal{R}^{n_1} \otimes \mathcal{R}^{n_2} \). For any 2-tensor \( T \), we can write it as:

\[
T = \sum_{\substack{1 \leq i \leq n_1 \\ 1 \leq j \leq n_2}} T_{ij} \varepsilon_i \otimes \tilde{\varepsilon}_j
\]

This shows that every 2-tensor in \( \mathcal{R}^{n_1} \otimes \mathcal{R}^{n_2} \) uniquely corresponds to a \( n_1 \times n_2 \) matrix. Given two vectors \( \mathbf{a} = \sum_{k=1}^{n_1} a_k \mathbf{e}_k \in \mathcal{R}^{n_1} \) and \( \mathbf{b} = \sum_{l=1}^{n_2} b_l \tilde{\mathbf{e}}_l \in \mathcal{R}^{n_2} \), we have

\[
T(\mathbf{a}, \mathbf{b}) = \sum_{ij} T_{ij} \varepsilon_i(\sum_{k=1}^{n_1} a_k \mathbf{e}_k) \tilde{\varepsilon}_j(\sum_{l=1}^{n_2} b_l \tilde{\mathbf{e}}_l)
\]

\[
= \sum_{ij} T_{ij} \varepsilon_i(\sum_{k=1}^{n_1} a_k \mathbf{e}_k) \tilde{\varepsilon}_j(\sum_{l=1}^{n_2} b_l \tilde{\mathbf{e}}_l)
\]

\[
= \sum_{ij} T_{ij} a_i b_j
\]

\[
= \mathbf{a}^T \mathbf{T} \mathbf{b}
\]

Note that, in this paper our primary interest is focused on the second order tensors. However, the algebra presented here and the algorithm presented in the next section can also be applied to higher order tensors.

### 2.2 Support Vector Machine

Support Vector Machines are a family of pattern classification algorithms developed by Vapnik [15] and collaborators. SVM training algorithms are based on the idea of \textit{structural risk minimization} rather than \textit{empirical risk minimization}, and give rise to new ways of training polynomial, neural network, and radial basis function (RBF) classifiers. SVM has proven to be effective for many classification tasks [7][12].

We shall consider SVMs in the binary classification setting. Assume that we have a data set \( D = \{ \mathbf{x}_i, y_i \}_{i=1}^m \) of labeled examples, where \( y_i \in \{-1, 1\} \), and we wish to select, among the infinite number of linear classifiers that separate the data, one that minimizes the generalization error, or at least minimizes an upper bound on it. It is shown that the hyperplane with this property is the one that leaves the maximum margin between the two classes. The discriminant hyperplane can be defined as

\[
f(\mathbf{x}) = \mathbf{w}^T \mathbf{x} + b
\]
where \( \mathbf{w} \) is a vector orthogonal to the hyperplane. Computing the best hyperplane is posed as a constrained optimization problem and solved using quadratic programming techniques. The optimization problem of SVM can be stated as follows:

\[
\min_{\mathbf{w}, b, \xi} \quad \frac{1}{2} \mathbf{w}^T \mathbf{w} + C \sum_{i=1}^{m} \xi_i \\
\text{subject to} \quad y_i (\mathbf{w}^T \mathbf{x}_i + b) \geq 1 - \xi_i, \quad i = 1, \ldots, m.
\]

Given a new data point \( \mathbf{x} \) to classify, a label is assigned according to its relationship to the decision boundary, and the corresponding decision function is

\[
g(\mathbf{x}) = \text{sign} \left( \mathbf{w}^T \mathbf{x} + b \right)
\]

3 TENSOR SPACE MODEL

Document indexing and representation has been a fundamental problem in information retrieval for many years. Most of previous works are based on the Vector Space Model (VSM, [13]). The documents are represented as vectors, and each word corresponds to a dimension. In this section, we introduce a new Tensor Space Model (TSM) for document representation.

In Tensor Space Model, a document is represented as a tensor. Each element in the tensor corresponds to a feature (word in our case). For a document \( \mathbf{x} \in \mathbb{R}^n \), we can convert it to the second order tensor (or matrix) \( \mathbf{X} \in \mathbb{R}^{n_1 \times n_2} \), where \( n_1 \times n_2 \approx n \). Figure 1 shows an example of converting a vector to a tensor. There are two issues about converting a vector to a tensor.

The first one is how to choose the size of the tensor, i.e., how to select \( n_1 \) and \( n_2 \). In figure 1, we present two possible tensors for a 9-dimensional vector. Suppose \( n_1 \geq n_2 \), in order to have at least \( n \) entries in the tensor while minimizing the size of the tensor, we have \( (n_1 - 1) \times n_2 < n \leq n_1 \times n_2 \). With such requirement, there are still many choices of \( n_1 \) and \( n_2 \), especially when \( n \) is large. Generally all these \( (n_1, n_2) \) combinations can be used. However, it is worth noticing that the number of parameters of a linear function in the tensor space is \( n_1 + n_2 \). Therefore, one may try to minimize \( n_1 + n_2 \). In other words, \( n_1 \) and \( n_2 \) should be as close as possible.

The second issue is how to sort the features in the tensor. In vector space model, we implicitly assume that the features are independent. A linear function in vector space can be written as \( g(\mathbf{x}) = \mathbf{w}^T \mathbf{x} \). Clearly, the change of the order of the features has no impact on the function learning. In tensor space model, a linear function can be written as \( f(\mathbf{X}) = \mathbf{u}^T \mathbf{X} \mathbf{v} \). Thus, the independency assumption of the features no longer holds for the learning algorithms in the tensor space model. Different feature sorting will lead to different learning result in the tensor space model.
Figure 1: Vector to tensor conversion. 1~9 denote the positions in the vector and tensor formats. (a) and (b) are two possible tensors. The ‘x’ in tensor (b) is a padding constant.

In this paper, we empirically sort the features (words) according to their document frequency and then convert the vector into a $n_1 \times n_2$ tensor such that $n_2 = 50$. The better ways of converting a document vector to a document tensor with theoretical guarantee will be left for our future work.

4 SUPPORT TENSOR MACHINES

4.1 The Problem

Given a set of training samples $\{X_i, y_i\}, i = 1, \cdots, m$, where $X_i$ is the data point in order-2 tensor space, $X_i \in \mathcal{R}^{n_1} \otimes \mathcal{R}^{n_2}$ and $y_i \in \{-1,1\}$ is the label associated with $X_i$. Find a tensor classifier $f(X) = u^T X v + b$ such that the two classes can be separated with maximum margin.

4.2 The Algorithm

STM is a tensor generalization of SVM. The algorithmic procedure is formally stated below:

1. **Initialization:** Let $u = (1, \cdots, 1)^T$.

2. **Computing $v$:** Let $x_i = X_i^T u$ and $\beta_1 = \|u\|^2$, $v$ can be computed by solving the following optimization problem:

$$\min_{v,b,\xi} \frac{1}{2} \beta_1 v^T v + C \sum_{i=1}^{m} \xi_i$$

subject to

$$y_i(v^T x_i + b) \geq 1 - \xi_i, \quad (4)$$

$$\xi_i \geq 0, \quad i = 1, \cdots, m.$$

*Note:* The optimization problem (4) is the same as (2) in the standard SVM algorithm. Thus, any computational method for SVM can also be used here.
3. Computing $u$: Once $v$ is obtained, let $\tilde{x}_i = X_i v$ and $\beta_2 = \|v\|^2$. $u$ can be computed by solving the following optimization problem:

$$\min_{u, b, \xi} \frac{1}{2} \beta_2 u^T u + C \sum_{i=1}^{m} \xi_i$$
subject to
$$y_i (u^T \tilde{x}_i + b) \geq 1 - \xi_i,$$
$$\xi_i \geq 0, \quad i = 1, \cdots, m.$$ (5)

Note: As above, the optimization problem (5) is the same as (2) in the standard SVM algorithm and we can use the computational methods for SVM to solve (5).

4. Iteratively computing $u$ and $v$: By step 2 and 3, we can iteratively compute $u$ and $v$ until they tend to converge.

Note: The convergence proof is given in Section 5.2.

5 JUSTIFICATIONS

In this section, we provide a justification of our STM algorithm.

5.1 Large Margin Classifier in Tensor Space

Suppose we have a set of order-2 tensors $X_1, \cdots, X_m \in \mathbb{R}^{n_1} \otimes \mathbb{R}^{n_2}$. A linear classifier in the tensor space can be naturally represented as follows:

$$f(X) = sign \left( u^T X v + b \right), \quad u \in \mathbb{R}^{n_1}, v \in \mathbb{R}^{n_2}$$ (6)

Equation (6) can be rewritten through matrix inner product as follows:

$$f(X) = sign \left( \langle X, uv^T \rangle + b \right), \quad u \in \mathbb{R}^{n_1}, v \in \mathbb{R}^{n_2}$$ (7)

Thus, the optimization problem in the tensor space is reduced to the following:

$$\min_{u, v, b, \xi} \frac{1}{2} \|uv^T\|^2 + C \sum_{i=1}^{m} \xi_i$$
subject to
$$y_i (u^T X_i v + b) \geq 1 - \xi_i,$$
$$\xi_i \geq 0, \quad i = 1, \cdots, m.$$ (8)

We will now switch to a Lagrangian formulation of the problem. We introduce positive Lagrange multipliers $\alpha_i, \mu_i, i = 1, \cdots, m$, one for each of the inequality constraints (8). This gives Lagrangian:

$$L_P = \frac{1}{2} \|uv^T\|^2 + C \sum_{i=1}^{m} \xi_i - \sum_{i}^{m} \alpha_i y_i (u^T X_i v + b)$$
$$+ \sum_{i}^{m} \alpha_i - \sum_{i}^{m} \alpha_i \xi_i - \sum_{i}^{m} \mu_i \xi_i$$
Note that
\[
\frac{1}{2} \|uv^T\|^2 = \frac{1}{2} \text{trace} \left( uv^T vu^T \right) = \frac{1}{2} (v^Tv) \text{trace} \left( uu^T \right) = \frac{1}{2} (v^Tv)(u^Tu)
\]

Thus, we have:
\[
L_P = \frac{1}{2} (v^Tv)(u^Tu) + C \sum \xi_i - \sum \alpha_i y_i (u^T X_i v + b)
+ \sum \alpha_i - \sum \alpha_i \xi_i - \sum \mu_i \xi_i
\]

Requiring that the gradient of \(L_P\) with respect to \(u, v, b\) and \(\xi\) vanish give the conditions:
\[
u = \frac{\sum \alpha_i y_i X_i v}{v^Tv}
\]
\[
v = \frac{\sum \alpha_i y_i u^T X_i}{u^Tu}
\]
\[
\sum \alpha_i y_i = 0
\]
\[
C - \alpha_i - \mu_i = 0, \quad i = 1, \cdots, m
\]

From Equations (9) and (10), we see that \(u\) and \(v\) are dependent on each other, and cannot be solved independently. In the following, we describe a simple yet effective computational method to solve this optimization problem.

We first fix \(u\). Let \(\beta_1 = \|u\|^2\) and \(x_i = X_i^T u\). Thus, the optimization problem (8) can be rewritten as follows:
\[
\min_{v, b, \xi} \frac{1}{2} \beta_1 \|v\|^2 + C \sum \xi_i
\]
subject to \(y_i (v^T x_i + b) \geq 1 - \xi_i, \quad \xi_i \geq 0, \quad i = 1, \cdots, m.
\]

It is clear that the new optimization problem (13) is identical to the standard SVM optimization problem. Thus, we can use the same computational methods of SVM to solve (13), such as [5][10][11].

Once \(v\) is obtained, let \(\beta_2 = \|v\|^2\) and \(\tilde{x}_i = Xv\). Thus, \(u\) can be obtained by solving the following optimization problem:
\[
\min_{u, b, \xi} \frac{1}{2} \beta_2 \|u\|^2 + C \sum \xi_i
\]
subject to \(y_i (u^T \tilde{x}_i + b) \geq 1 - \xi_i, \quad \xi_i \geq 0, \quad i = 1, \cdots, m.
\]

</table>

Again, we can use the standard SVM computational methods to solve this optimization problem. Thus, \( \mathbf{v} \) and \( \mathbf{u} \) can be obtained by iteratively solving the optimization problems (13) and (14). In our experiments, \( \mathbf{u} \) is initially set to the vector of all ones.

By comparing the optimization problems of SVM (2) and STM (8), also noting that \( X_i \) in (8) is converted from \( x_i \) in (2) through the “vector-to-tensor” conversion described in Section 3, STM can be thought of as a special case of SVM with the following constraint:

\[
W_{n_1(j-1)+i} = u_i v_j
\]  

(15)

For \( n \)-dimensional documents, the \( \mathbf{w} \) in decision function of SVM is also \( n \)-dimensional, so there are \( n + 1 \) (\( \approx n_1 \times n_2 + 1 \)) parameters for SVM. For STM, there are only \( n_1 + n_2 + 1 \) parameters. Therefore, STM is much more computationally tractable and especially suitable for small sample cases.
5.2 Convergence Proof

In this section, we provide a convergence proof of the iterative computational method described above. We have the following theorem:

**Theorem 1** The iterative procedure to solve the optimization problems (13) and (14) will monotonically decreases the objective function value in (8), and hence the STM algorithm converges.

**Proof** Define:

\[ f(u, v) = \frac{1}{2} \| uv^T \|^2 + C \sum_{i=1}^{m} \xi_i \]

Let \( u_0 \) be the initial value. Fixing \( u_0 \), we get \( v_0 \) by solving the optimization problem (13). Likewise, fixing \( v_0 \), we get \( u_1 \) by solving the optimization problem (14).

Notice that the optimization problem of SVM is convex, so the solution of SVM is globally optimum \([1][4]\). Specifically, the solutions of equations (13) and (14) are globally optimum. Thus, we have:

\[ f(u_0, v_0) \geq f(u_1, v_0) \]

Finally, we get:

\[ f(u_0, v_0) \geq f(u_1, v_0) \geq f(u_1, v_1) \geq f(u_2, v_1) \geq \cdots \]

Since \( f \) is bounded from below by 0, it converges. \( \square \)

5.3 From Matrix to High Order Tensor

The STM algorithm described above takes order-2 tensors, i.e., matrices, as input data. However, the algorithm can also be extended to high order tensors. In this section, we briefly describe the STM algorithm for high order tensors.

Let \((T_i, y_i), i = 1, \cdots, m\) denote the training samples, where \( T_i \in \mathcal{R}^{n_1} \otimes \cdots \otimes \mathcal{R}^{n_k} \). The decision function of STM is:

\[ f(T) = T(a^1, a^2, \cdots, a^k) + b \]

\[ a^1 \in \mathcal{R}^{n_1}, a^2 \in \mathcal{R}^{n_2}, \cdots, a^k \in \mathcal{R}^{n_k} \]

where

\[ T(a^1, a^2, \cdots, a^k) = \sum_{1 \leq i_1 \leq n_1} T_{i_1, \cdots, i_k} a^1_{i_1} \times \cdots \times a^k_{i_k} \]

As before, \( a^1, \cdots, a^k \) can also be computed iteratively.

We first introduce the \( l \)-mode product of a tensor \( T \) and a vector \( a \), which we denote as \( T \times_l a \). The result of \( l \)-mode product of a tensor \( T \in \mathcal{R}^{n_1} \otimes \cdots \otimes \mathcal{R}^{n_k} \) and a vector \( a \in \mathcal{R}^{n_l}, 1 \leq l \leq k \) will

be a new tensor $B \in \mathcal{R}^{n_1} \otimes \cdots \otimes \mathcal{R}^{n_{l-1}} \otimes \mathcal{R}^{n_{l+1}} \otimes \cdots \mathcal{R}^{n_k}$, where

$$B_{i_1,\ldots,i_{l-1},i_{l+1},\ldots,i_k} = \sum_{i_l=1}^{n_l} T_{i_1,\ldots,i_{l-1},i_l,i_{l+1},\ldots,i_k} a_{i_l}$$

Thus, the decision function in higher order tensor space can also be written as:

$$f(T) = T \times_1 a^1 \times_2 a^2 \cdots \times_k a^k + b$$

The optimization problem of STM in high order tensors is:

$$\min_{a^1,\ldots,a^k,b,\xi} \frac{1}{2} \|a^1 \otimes \cdots \otimes a^k\|^2 + C \sum_{i=1}^{m} \xi_i$$

subject to

$$y_i(T_i(a^1, a^2, \ldots, a^k) + b) \geq 1 - \xi_i,$$

$$\xi_i \geq 0, \quad i = 1, \ldots, m.$$ 

Here $\|a^1 \otimes \cdots \otimes a^k\|$ denotes the tensor norm of $a^1 \otimes \cdots \otimes a^k$ [8].

First, to compute $a^1$, we fix $a^2,\ldots,a^k$. Let $\beta_2 = \|a^2\|^2, \ldots, \beta_k = \|a^k\|^2$. We then define

“≫” or “≪” means P-value ≤ 0.01
“>” or “<” means 0.01 < P-value ≤ 0.05
“∼” means P-value > 0.05

t_i = T_i \times a^2 \times a^k. Thus, the optimization problem (16) can be reduced as follows:

\[
\begin{aligned}
\min_{a^1, b, \xi} \quad & \frac{1}{2} \beta_2 \cdots \beta_k \| a^1 \|^2 + C \sum_{i=1}^{m} \xi_i \\
\text{subject to} \quad & y_i (a^{1T} t_i + b) \geq 1 - \xi_i, \\
\quad & \xi_i \geq 0, \quad i = 1, \ldots, m.
\end{aligned}
\] (17)

Again, we can use the standard SVM computational methods to solve this optimization problem. Once \(a^1\) is computed, we can fix \(a^1, a^3, \cdots, a^k\) to compute \(a^2\). So on, all the \(a^i\) can be computed in such iterative manner.

### 6 EXPERIMENTS

In this section, several experiments were performed to show the effectiveness of our proposed algorithm. Two standard document collections were used in our experiments:Reuters-21578 and TDT2. We compared our proposed algorithm with Support Vector Machines.
6.1 Data Corpora

Reuters-21578 corpus\(^1\) contains 21578 documents in 135 categories. The ModApte version of Reuters-21578 is used in our experiments. Those documents with multiple category labels are discarded, and the categories with more than 10 documents are kept. It left us with 8213 documents in 41 categories as described in Table 1. For ModeApte split, there are 5899 training documents and 2314 testing documents. After preprocessing, this corpus contains 18933 distinct terms.

The TDT2 corpus\(^2\) consists of data collected during the first half of 1998 and taken from six sources, including two newswires (APW, NYT), two radio programs (VOA, PRI) and two television programs (CNN, ABC). It consists of 11201 on-topic documents which are classified into 96 semantic categories. In this dataset, we also removed those documents appearing in two or more categories and use the categories which contain more than 10 documents thus leaving us with 10021 documents in 56 categories as described in Table 2. After preprocessing, this corpus contains 36771 distinct terms.

Each document is represented as a term-frequency vector and each document vector is normalized to 1. We simply removed the stop words, and no further preprocessing was done. For STM, we empirically sort the features (words) according to their document frequency and then convert the vector into a \(n_1 \times n_2\) tensor such that \(n_2 = 50\).

6.2 Evaluation Metric

The classification performance is evaluated by comparing the predicted label of each testing document with that provided by the document corpus. The standard recall, precision and \(F_1\) measure are used here [17]. Recall is defined to be the ratio of correct assignments by the classifier divided by the total number of correct assignments. Precision is the ratio of correct assignments by the classifier divided by the total number of the classifier’s assignments. The \(F_1\) measure combines recall \((r)\) and precision \((p)\) with an equal weight in the following form:

\[
F_1(r, p) = \frac{2rp}{r + p}
\]

These scores can be computed for the binary decisions on each individual category first and then be averaged over categories. Or, they can be computed globally over all the \(n \times m\) binary decisions where \(n\) is the number of total test documents, and \(m\) is the number of categories in consideration. The former way is called *macro-averaging* and the latter way is called *micro-averaging*. It is understood that the micro-averaged scores tend to be dominated by the classifier’s performance on common categories, and the macro-averaged scores are more influenced by the performance on rare categories. Providing both kinds of scores is more informative than providing either alone.

\(^1\)Reuters-21578 corpus is at [http://www.daviddewilde.com/resources/testcollections/reuters21578/](http://www.daviddewilde.com/resources/testcollections/reuters21578/)

We also use a set of significance tests for comparing two classification methods with various performance measures. These significance tests are:

- **Micro sign test (s-test):** A sign test designed for comparing two systems, A and B, based on their decisions on all the document/category pairs.

- **Macro sign test (S-test):** A sign test for comparing two systems, A and B, using the paired $F_1$ values for individual categories.

- **Macro t-test (T-test):** A t-test for comparing two systems, A and B, using the paired $F_1$ values for individual categories.

For more details about these significance tests, please refer to [18].

### 6.3 Experimental Results

We used the LIBSVM system [3] and tested it with the linear model, since previous researches [18] show that linear SVM is effective enough for text categorization.

The dataset was randomly split into training and testing sets. In order to examine the effectiveness of the proposed algorithm with different size of the training set, we ran several tests that the

</tbody>
</table>

training set contains 5%, 10%, 30% and 50% documents, for both Reuters-21578 and TDT2. In all these splits, we kept at least two documents in every category of the training set. For each test, we averaged the results over 10 random splits. Moreover, for Reuters-21578 dataset, we also tested on the ModApte split which contains around 70% training sample.

Table 3 and 5 show the classification results on two datasets. Table 4 and 6 summarized the statistical significance tests. Figure (2,3,4,5) show the performance with respect to the training set size.

As can be seen from the above results, when the training set is small (5% and 10%), STM outperforms SVM on both micro-averaged $F_1$ and macro-averaged $F_1$. As the number of training samples increases, STM performed better than SVM on macro-averaged $F_1$ but worse on micro-averaged $F_1$.

As we know, the micro-level measure is dominated by the performance of the classifiers on large categories, while the macro-level measure is more sensitive to the performance of the classifiers on small categories [18]. The experimental results show the greater performance of STM on small training sample cases over SVM.

To get a more detailed picture of the performance difference between STM and SVM over different size of training samples, we plot the performance curves of STM and SVM over different categories in Figure 6 and 7. The categories are sorted by the number of training samples. For those categories with the same number of training samples, we averaged their $F_1$ scores. We can
Figure 4: Micro-averaged F1 on TDT2 dataset

Figure 5: Macro-averaged F1 on TDT2 dataset

see that STM is better than SVM on the left side of the figures (corresponding to small training set) but worse than SVM on the right side of the figures. This observation indicates that our STM algorithm is especially suitable for small sample problems. This is due to the fact that the number of parameters need to be estimated in STM is $n_1 + n_2 + 1$ which can be much smaller than $n_1 \times n_2 + 1$ in SVM.

7 Conclusions

In this paper we have introduced a tensor framework for document representation and classification. In particular, we have proposed a new classification algorithm called Support Tensor Machines (STM) for learning a linear classifier in tensor space. Our experimental results on Reuters-21578 and TDT2 databases demonstrate that STM is especially suitable for small sample cases. This is due to the fact that the number of parameters estimated by STM is much less than that estimated by standard SVM.

There are several interesting problems that we are going to explore in the future work:

1. In this paper, we empirically construct the tensor. The better ways of converting a document vector to a document tensor with theoretical guarantee need to be studied.
Figure 6: Performance curves of all categories on Reuters-21578 dataset (30% training samples case)

2. STM is a linear method. Thus, it fails to discover the nonlinear structure of the data space. It remains unclear how to generalized our algorithm to nonlinear case. A possible way of nonlinear generalization is to use kernel techniques.

3. In this paper, we use a iterative computational method for solving the optimization problem of STM. We expect that there exists more efficient computational methods.
