1. Introduction

E-science or cyberinfrastructure have become crucial for scientific progress and open source systems have greatly facilitated design and implementation. In chemistry, the growth of data has been explosive and timely and effective information and data access is critical [Atkins 2003, Hey 2006]. Many have argued that cyberinfrastructures for science are domain sensitive [Snow 2006] and many have been proposed. We have proposed and are developing the Chem\textsubscript{3}Seer architecture, a portal for academic researchers in environmental chemistry, which integrates the scientific literature with experimental, analytical and simulation datasets. Chem\textsubscript{3}Seer will be comprised of information crawled from the web, manual submission of scientific documents and user submitted datasets, as well as scientific documents and metadata provided by major publishers. Information crawled by Chem\textsubscript{3}Seer from the web and user submitted data will be publicly accessible whereas access to publisher resources can be provided by linking to their respective sites. Thus, instead of being a fully open search engine and repository, Chem\textsubscript{3}Seer will be a hybrid one, limiting access to some resources.

2. Chemistry and Cyberinfrastructure

Chemical research is becoming increasingly collaborative in scope and approach. For example, within the Penn State Center for Environmental Kinetics Analysis (CEKA), researchers are taking a multi-disciplinary approach to linking kinetic information in environmental chemistry across spatial and temporal scales (see www.cea.psu.edu for more information). A main goal of such research is to integrate experimental, analytical, and simulation results performed on systems from molecular to field scales in order to better approximate the complex physical, chemical, and biological interactions controlling the fate and transport of contaminants. Researchers in this area have realized for some time that new scientific questions can be generated when users have access to a broad spectrum of related results. Subsequently, as connections are made among field observations, experimental kinetic results, spectroscopic analyses, and model predictions, gaps in the information web will become apparent. Approaches to filling these gaps can then be addressed by the collaborative team. In addition, when inconsistencies among results are identified through use of databases and collaboration tools, determining the reasons for these differences can motivate and guide researchers to formulate experiments to eliminate discrepancies or make new discoveries. In short, data collection and synthesis will lead to better science and improved education of scientists.

Academic chemistry is now focusing on cyberinfrastructure in many areas, with a focus on building tools that are open source and shared within their community. There is much interest on chemistry web services [Coles 2005], chemical markup languages [Murray-Rust 2001], chemical ontologies [Chebi], chemical literature indexing and search [PubChem], data repositories [Fletcher 1996, Afeefy 2005], chemistry notebooks [Hughes 2004], and others. As part of this wave of development, the Chem\textsubscript{3}Seer system will focus on the needs of domain scientists in chemistry, especially the interdisciplinary needs that arise when addressing complex kinetics synthesis problems.

3. The Chem\textsubscript{3}Seer System

Chem\textsubscript{3}Seer intends to offer unique aspects of search not yet present in other scientific search services. We have developed or are developing algorithms for the extraction of tables, figures, equations and formulae from scientific documents enabling users to search on those fields. Chem\textsubscript{3}Seer intends to or currently does provide the following search features:

- Full text search
- Author, affiliation, title and venue search
- Figure search
- Table search
- Formulae search
- Citation and acknowledgement search
- Citation linking and statistics

A beta version of Chem\textsubscript{3}Seer is online and working.

4. Data Search

For dataset search, we are developing tools that automatically annotate published data representations such as figures and that permit researchers to annotate their datasets by providing both document-level and attribute-level metadata in OAI-PMH format [Jaiswal 2006]. This level of data annotation provides us with the opportunity of searching data more effectively both at the attribute and semantic levels, browsing datasets and linking to existing scientific literature and other datasets in our and other repositories. The data search feature is now available as a beta in Chem\textsubscript{3}Seer.

5. Chemical Formula Search
Current search engines do not recognize chemical entities (chemical names and formulae). A scientist, who seeks to search for information related to chemical molecules from text documents cannot do so in any meaningful way except performing exact keyword search. We show how a chemical-entity-aware search engine can be designed and built and demonstrate empirically that it improves the relevance of the returned results for search queries involving chemical entities. Our search engine first extracts chemical entities from text, performs a novel indexing suitable for chemical formulae and names, and supports different query models that a scientist may require. We develop a model of hierarchical conditional random fields (HCRFs) for entity tagging that considers long-term dependencies at the higher (hierarchical) levels. Experiments and examples show that our approach performs reasonably well [Sun 2007]. A beta of formula search is now available in ChemXSeer.

6. Table Search

Tables are ubiquitous in scientific documents where they are widely used to present experimental results or statistical data in a condensed fashion. However, current search engines do not support table search. Scientists and scholars often extract data from tables in documents by hand. We have created a table search engine (TableSeer) that eliminates that burden enabling users to automatically search for and examine tables. TableSeer crawls scientific documents, detects tables from documents, extracts and indexes tables metadata, and enables end-users to search for tables. We also propose an extensive set of medium-independent metadata for tables because there exists no tablemarkup language and universal metadata specification for tables that scientists and other users can adopt for representing table information in documents. We demonstrate the value of our specialized table-search engine by empirical studies using scientific documents [Liu 2006, 2007]. A beta of TableSeer is now available in ChemXSeer.

7. Figure Search

Like tables, much important information in documents resides in figures. We are interested in all of figure search. However, our current focus is on searching for and extracting data from plots. Two-dimensional (2-D) plots in digital documents contain important information. Often, the results of scientific experiments and performance of businesses are summarized using plots. Although 2-D plots are easily understood by users, current search engines rarely utilize the information contained in the plots to enhance the results returned in response to queries. We have developed an automated algorithm for extracting information from line curves in 2-D plots. Experimental evaluation has demonstrated that our method can produce results suitable for real world use [Lu 2006, Lu 2007]. We intend to make a beta for plot search available in ChemXSeer.

7. Search Integration

Integration of search results is a nontrivial issue. We propose to investigate new methods for integrating chemical search based on molecular centric views permitting users to have easy access to all related information [Bolelli 2007]. We also intend to link search results to other available databases.

8. Conclusions

ChemXSeer is an ongoing cyberinfrastructure project in chemistry. By offering chemists automatic access to information and data not previously available, ChemXSeer will change the way chemists do research and will significantly enhance scientific productivity and contribute to new discoveries.

9. Acknowledgements

The ChemXSeer cyberinfrastructure research and project is supported in part by a grant from NSF Chemistry.
