DEVELOPMENTS IN ILLINOIS AND INDIANA IN 1953¹

ALFRED H. BELL² AND T. A. DAWSON³
Urbana, Illinois, and Bloomington, Indiana

ABSTRACT

In Illinois and Indiana, 3,473 wells were drilled for oil and gas in 1953, as compared with 3,357 in 1952, an increase of 3 per cent. Total oil production decreased $\frac{1}{2}$ of 1 per cent, from 72,008,000 barrels in 1952 to 71,606,000 barrels in 1953. Exploratory drilling decreased from 1,181 completions in 1952 to 949 in 1953. Forty-nine new pools, 63 extensions, and 20 new producing zones were discovered in the two states in 1953.

As in previous years, most of the discoveries in 1953 were in Mississippian formations. Six new pools produced from Pennsylvanian sandstones, 3 from Devonian or Silurian limestones, and 1 from Ordovician limestone.

INTRODUCTION

In Illinois and Indiana, 3,473 wells were drilled for oil and gas in 1953, as compared with 3,357 in 1952, an increase of 3 per cent. Total oil production decreased $\frac{1}{2}$ of 1 per cent, from 72,008,000 barrels in 1952 to 71,606,000 barrels in 1953. Exploratory drilling decreased from 1,181 completions in 1952 to 949 in 1953. Forty-nine new pools, 63 extensions, and 20 new producing zones were discovered in the two states in 1953.

In the Illinois basin area (southern Illinois and southwestern Indiana) 39 out of 49 discovery wells of new pools produced from Mississippian formations (30 in the Chester series and 9 in the Lower Mississippian). Of the other 10 discovery wells of new pools, 6 produced from Pennsylvanian sandstone, 3 from Devonian or Silurian limestone, and 1 from Ordovician limestone.

ILLINOIS

By ALFRED H. BELL

In Illinois 2,161 wells were drilled for oil and gas in 1953 as compared with 2,077 in 1952, an increase of 4 per cent. (These figures are exclusive of water- or gas-input wells, salt-water disposal wells, and old wells worked over.) This drilling resulted in 1,068 oil wells, 5 gas wells, and 1,088 dry holes.

Of the 2,161 wells drilled, 533 were wildcats, as compared with 663 in 1952, showing a decrease of 20 per cent in 1953. Of the wildcat wells in 1953, 169 were drilled more than 2 miles from production ("wildcats far"), of which 11, or 6.5 per cent, were successful. In 1952, 3.1 per cent were successful.

An effective new method of completing wells by hydraulic fracturing came into wide use in Illinois in 1953, when 54 per cent of all completed wells were reported to be so treated. To it is attributable, at least in part, the significant increase—from 3.1 per cent in 1952 to 6.5 per cent in 1953—of successful wildcat wells more than 2 miles from production and the rise in producers—from 39.5

^a Oil and water.

per cent in 1952 to 49.5 per cent in 1953—of total completions. Fracture treatment has resulted in commercial production from wells which could not otherwise have been operated profitably. However, the process is not always commercially successful; there are instances where there is not enough increased productivity to offset the cost of the treatment.

So far, the formation which seems to have responded best to fracture treatment is the Aux Vases sandstone, which is characteristically fine-grained and of low permeability. There were many completions of fracture-treated wells in the Aux Vases formation in a part of the Clay City Consolidated field east and northeast of Fairfield.

Of the 533 wildcat wells drilled, 23 discovered new pools, and 40 discovered extensions to pools (Tables I and II). Four new pools and 7 extensions were discovered by old wells worked over. In addition, 13 wells, most of which can not properly be classified as exploratory wells, discovered additional producing zones in known producing areas (Table III).

Most of the drilling for oil and gas in Illinois in 1953, as in previous years, was in the structural basin of southern Illinois. Wells were drilled in 47 of the state's 102 counties, and producing wells were drilled in 31 counties. More than half the wells completed in 1953 were concentrated in 6 counties: Wayne, 383; White, 247; Marion, 120; Clay, 119; Edwards, 119; and Wabash, 115. More producing wells were completed in Wayne County than total completions, including dry holes, in any other county.

There were no major pools among the 27 discovered in Illinois in 1953 (Table I). The largest pools were Irvington North, Washington County, with 13 wells at the end of the year, Patoka South, Marion County, with 12 wells at the end of the year, and Raleigh, Saline County, with 7 wells at the end of the year. Two pools were abandoned before the end of the year. The others had only from 1 to 3 wells each. Total number of wells in all the new pools was 62 on December 31, 1953.

Total oil production in Illinois in 1953 was 59,025,000 barrels as compared with 60,071,000 barrels in 1952, a decrease of 1.7 per cent. Average daily production was 162,000 barrels in 1953 as compared with 164,000 barrels in 1952.

EXPLORATORY DRILLING

Exploratory wells were drilled in 47 counties in Illinois in 1953 and new pools were discovered in 17 counties. All but 2 of the 47 counties in which exploratory wells were drilled are in the southern two-thirds of the state. Most of the new pools discovered in 1953 are within 2 or 3 miles of previous production. Exceptions are Decatur, Macon County (Table I, No. 7), 9 miles from previous production, Blackland, Macon County (Table I, No. 5), 9 miles from previous production, Prentice, Morgan County (Table I, No. 23), 4 miles from previous production, and Melrose, Clark County (Table I, No. 17), 6 miles from previous production.

Four new pools in Illinois produce from Pennsylvanian sandstones: Dudley

* Plugged back to production.

West, Edgar County; Melrose and Melrose South, Clark County; and Prentice, Morgan County. Two new pools produce from Devonian or Silurian limestones, Blackland and Decatur, both in Macon County. One new pool, Posen North, Washington County, produces from the Trenton limestone. All the other new pools produce from the Mississippian.

Additional producing zones in pools in Illinois discovered in 1953 were all of Mississippian age (Table III). Of these, 8 were Chester sandstones and the remainder were Lower Mississippian limestones.

Some noteworthy exploratory wells which were non-productive in the deeper formations tested are listed in Table IV. The deepest of these, which reached a depth of 5,074 feet (Table IV, No. 12), tested the Plattin formation in the Woodlawn pool, Jefferson County. Four wells (Table IV, Nos. 3, 10, 14 and 17) were drilled to formations below the St. Peter sandstone. There were several dry Devonian tests in pools in the basin area (Table IV, Nos. 4, 5 and 21).

METHODS OF EXPLORATION

The principal methods used in locating exploratory wells continued to be subsurface geology and the reflection seismograph (Table V). The amount of seismograph work in 1953 was 50 crew-months as compared with 72 crew-months in 1952. Gravity-meter work decreased from 14 crew-months in 1952 to 2 crew-months in 1953.

FIG. 1.—Oil and gas pools in Illinois and Indiana.

Numbers indicate new pools discovered in 1953 (see Tables I and VIII).

INDIANA

By T. A. DAWSON

Oil production in Indiana during 1953 totaled 12,581,000 barrels as compared with 11,937,000⁴ barrels during 1952. Thus, during 1953, production increased 644,000 barrels, or 5.4 per cent.

Drilling in Indiana during 1953 totaled 1,312 wells. Little change in either the totals or results of exploratory and development drilling occurred between 1952 and 1953 (Table VII). Of the 1,312 wells drilled, 416 were wildcats; 22 of the wildcat wells resulted in new-pool discoveries (Table VIII) and 16 resulted in exten-

TABLE VII. COMPLETION SUMMARY FOR INDIANA FOR 1952 AND 1953

	<i>Oil</i>	<i>Gas</i>	<i>Dry</i>	<i>Total</i>	<i>Percentage Successful</i>
1952 Exploratory wells	53	5	358	416	13.9
Development wells	382	19	465	866	47.5
Total	435	24	823	1,282	
1953 Exploratory wells	41	4	371	416	10.8
Development wells	417	27	452	896	49.6
Total	458	31	823	1,312	

sions to pools (Table IX). In addition, 7 wildcat wells resulted in additional pay-zone discoveries in productive areas (Table X). During 1952, 416 wildcat wells were drilled, resulting in 21 new-pool discoveries, 17 extensions to pools, and 20 additional pay-zone discoveries. The percentage of wildcats that were successful in 1953 was 10.8, whereas in 1952 the percentage was 13.9 (Table VII). However, if additional pay-zone discoveries are excluded (and there is doubt that they should be classified as exploratory wells), approximately 9 per cent of all wildcat wells were successful in both 1952 and 1953.

Wells were drilled in 45 of the state's 92 counties. More than two-thirds of the wells, however, were drilled in five counties in the southwestern part of the state: 235 wells in Gibson County; 230 in Posey County; 185 in Pike County; 142 in Spencer County; and 104 in Dubois County. The only other counties that had more than 50 wells were Knox with 75 and Vigo with 61.

Although exploratory wells were drilled in 30 counties, in only 11 counties were the exploratory wells successful. Of the 45 successful exploratory wells, 32 were drilled in four counties. Posey and Spencer counties each had 10 successful exploratory wells; Gibson and Dubois each had 6; Pike had 4; Vanderburgh had 3; Boone had 2 (both gas); and Clay, Daviess, Knox, and Perry had 1 each.

Most of the successful exploratory wells were completed in beds of Mississippian age. Of the 22 new-pool discovery wells, 19 were completed in the Mississippian (15 in the Chester and 4 in the Ste. Genevieve), 1 in the Devonian, and 2 in the Pennsylvanian. Of the 16 extensions, 14 were completed in the Mississippian (9 in the Chester and 5 in the Ste. Genevieve), and 2 in the Trenton. All

⁴ Does not include Trenton area.

TABLE XI. SELECTED LIST OF DRY TESTS IN INDIANA IN 1953

County	Company and Farm	Location	Total Depth (Feet)	Deepest Formation Tested
1. Spencer	Lohman-Johnson Drlg. Co. Inc. 1 Peter C. Bergenroth	2-6S-4W	2,348	Devonian ls.
2. Vigo	James G. Beard 1 Chicago, Milwaukee, St. Paul & Pacific Railroad	3-12N-9W	1,722	Silurian

7 new pays were completed in the Mississippian (6 in the Chester and 1 in the Salem).

Many of the successful exploratory wells resulted in only very limited development. However, 3 new pools, 2 extensions, and 1 new pay are noteworthy. Huntingburg South (new pool), with 6 wells producing from the Ste. Genevieve limestone, has a daily production of 82 barrels and a cumulative production of 35,370 barrels. King North (new pool), with 13 wells producing from the Aux Vases, has a daily production of 262 barrels and a cumulative production of 78,071 barrels. Mumford Hills East (new pool), with 4 wells producing from the Aux Vases, has a daily production of 179 barrels and a cumulative production of 21,774 barrels. Development in the extension area of Huntingburg resulted in 8 wells producing from the Aux Vases; these wells have a daily production of 142 barrels and a cumulative production of 60,139 barrels. Development in the extension area of Rock Hill resulted in 27 wells producing from the Tar Springs sand; these wells have a daily production of 284 barrels and a cumulative production of 53,332 barrels. Development in the new pay of Petersburg West resulted in 13 wells producing from the Bethel sand; these wells have a daily production of 183 barrels and a cumulative production of 101,034 barrels.

Few significant dry holes were drilled. Two, however, are worthy of mention (Table XI). The Lohman-Johnson Drilling Company's Peter C. Bergenroth No. 1 was a Devonian test in the Troy pool, and James G. Beard's Chicago, Milwaukee, St. Paul & Pacific Railroad's No. 1 was a Devonian test in the reef area of Vigo County. Both of these wells were drilled on structural features; the latter was drilled on a very pronounced reef structure. As all Devonian production in Indiana is associated with structure, these two wells probably will have a dampening influence on exploration for Devonian oil in the areas in which they were drilled.

Subsurface geology was the principal exploration tool used in Indiana. Nevertheless, core-drilling continued to be an important tool in areas where data indicate that structure is necessary to oil accumulation. Fairly large core-drilling programs were carried on in the reef area of Sullivan and Vigo counties and in the part of northern Indiana that lies within the Michigan basin. Little geophysical work was done.

Leasing activity increased appreciably in only two areas of Indiana—the Spencer-Dubois area, where successful exploratory drilling caused brisk lease plays, and the Michigan basin area, where several thousand acres are reported to have been leased in connection with core-drilling programs.

Drilling in Indiana would have slumped during 1953 had it not been for the greatly increased activity in Spencer and Dubois counties. Drilling in these two counties jumped from 47 wells in 1952 to 246 wells in 1953. Reservoir beds are shallower in the Spencer-Dubois area than in the Posey-Gibson area on the west. (Increased activity in this area of relatively shallow reservoirs is reflected in the average depth of all wells drilled; the 1,780-foot average for 1952 dropped to a

1,625-foot average for 1953.) Productivity of wells in the Spencer-Dubois area is very favorably comparable with that of wells in other areas; the average initial production of successful exploratory wells in the Spencer-Dubois area was 67 barrels as compared with 70 barrels for all successful exploratory wells. Moreover, a nearly complete Chester section, containing multiple potential reservoirs, is present in the Spencer-Dubois area. Because of shallow reservoirs, productive reservoirs, and multiple reservoirs, activity in the Spencer-Dubois area should remain relatively high and do much toward sustaining the drilling tempo in Indiana.
