

MILLIMETER-WAVE SPECTROSCOPY AND GLOBAL ANALYSIS OF THE LOWEST EIGHT VIBRATIONAL STATES OF DEUTERATED HYDRAZOIC ACID (DN₃)

BRENT K. AMBERGER, R. CLAUDE WOODS, BRIAN J. ESSELMAN, ROBERT J. McMAHON, *Department of Chemistry, University of Wisconsin, Madison, WI, USA.*

Hydrazoic acid (HN₃) and DN₃ have qualitatively different rotational spectra, owing in large part to a substantial difference in their *A* rotational constants (345 GHz for DN₃ vs 611 GHz for HN₃). Like HN₃, DN₃ has six fundamental vibrational modes, of which four are visible in our millimeter-wave spectra at room temperature. Between 240 and 450 GHz, many pure rotational transitions for the ground vibrational state, ν_5 (496 cm⁻¹), ν_6 (586 cm⁻¹), ν_4 (955 cm⁻¹), ν_3 (1197 cm⁻¹), the first overtones of ν_5 and ν_6 , and the combination $\nu_5+\nu_6$ have been observed and assigned. Because DN₃ is a light molecule, the rotational energy levels are widely spaced, leading to numerous interactions between rotational states of different vibrational modes. We have drawn on a wealth of previously published ro-vibrational data from high resolution FTIR spectra^{a,b,c,d} in our efforts to understand these perturbations. The centrifugal distortion interaction between ν_5 and the ground state of DN₃ is less dramatic than in HN₃ but still significant. DN₃ shows the same set of Coriolis interactions as does HN₃, but again, their magnitude is generally smaller. In DN₃ the ν_4 state is at slightly lower energy than $2\nu_5$, instead of being nearly degenerate with $\nu_5+\nu_6$ as is the case for HN₃. Therefore, there are strong local interactions between $2\nu_5$ and ν_4 , as well as between ν_3 and $2\nu_6$. A notable advantage in solving the DN₃ problem compared to HN₃ is the substantial increase in the number and diversity of observable *b*-type lines in our frequency region. Furthermore, the smaller *A* value permits higher *K* states to be observed due to a more gradual decrease in state populations. Ground state observations have been extended through *K* = 11 and through *J* = 50. Pickett's SPFIT has been employed to carry out multi-state fits using combined datasets of our millimeter-wave data and the published FTIR data.
